

OpenAI Specification — Best Invest Properties

Version: 1.5

Date: 2 October 2026

API: OpenAI Responses API

Called through: Make

Publication: only after admin review

1. What OpenAI does on the platform

OpenAI works in **two separate stages**:

1. **Proposed inputs and assessments.** From the property data and the source materials it is given, OpenAI proposes figures and assessments for the admin to check.
2. **Analysis text.** After the admin has approved the values and the score, OpenAI writes the readable **Investment Analysis** text.

How it works:

1. Make sends OpenAI the property data and the source materials, each with its link and date (section 4.1), together with the fixed Stage 1 instructions (section 5.1).
2. OpenAI returns proposals in a fixed structure (section 6.1). Each proposal has its sources and assumptions. Where there is no source, the item is marked as a gap.
3. The platform checks the proposals automatically, and saves them as **"awaiting review"**.
4. The admin checks and corrects the proposals. Bubble then applies the fixed formulas for the yield and the score to the approved values.
5. Make sends OpenAI the approved figures with all their components, the score, the admin-approved explanation and sources for each assessment, and the reviewed facts (section 4.2), together with the fixed Stage 2 instructions (section 5.2).
6. OpenAI returns the text in a fixed structure (section 6.2). The platform checks it automatically: every statement must point to a supplied fact, no new numbers may appear, and words like "guaranteed" or "risk-free" are not allowed.
7. The admin reviews the text and approves it. Only then do investors see it.

OpenAI does **not**:

- apply the formulas for acquisition cost and yield, or set the Rental Yield score or the Investment Score;
- invent a figure, a score or a source — without a source, a figure is marked as a gap and a score as needing review;
- decide on its own what a "good investment" is;
- search the internet;
- see the investor's name, email, phone or any other investor data, or the contact details of developer representatives;
- publish anything, or have anything used, without admin approval;
- replace a financial, legal or investment adviser.

If OpenAI is unavailable, unchecked data is not published. Approved figures stay visible, and the property page still shows the five criterion scores with the note "Narrative analysis is being reviewed".

2. What is in the MVP

Stage 1 — proposed inputs and assessments for the admin to check:

- the expected monthly rent;
- annual operating costs;
- the data needed for the total acquisition cost (purchase taxes and costs);
- the estimated fair market value, from comparable properties, with a reliability note;
- a score of **0, 1 or 2** for each of the four criteria that need judgement — **Price, Rental Demand, Capital Growth** and **Owner Protection & Eviction Efficiency** — following the score descriptions in the Project Specification (6.3), each with an explanation, the input data used and its sources. For Rental Demand, the scale used (Long Term or Short Term) is stated with the score.

The **Rental Yield** score is not proposed by AI: the platform sets it from the approved net yield. The Investment Score (0–10) is calculated by the platform as the sum of the five approved scores. Where the evidence is insufficient, the criterion is returned as **needing review** with no score; missing data is never scored as 0. The country examples in the Owner Protection descriptions are not an automatic country-to-score rule and are not treated as checked legal facts.

Every proposal is based only on the supplied source materials and has its sources and assumptions. The developer's claimed rent is never used as the proposed rent. These proposals appear on the Project Review screen next to their sources. The admin approves or corrects each one before it is used.

Stage 2 — the investment analysis text:

- a short neutral summary;
- 2–4 strengths, each linked to the facts it is based on;
- 1–4 risks or limitations;
- an explanation of the score, without changing it;
- a list of missing data;
- the standard disclaimer.

Not in the MVP:

- rewriting developer descriptions with AI;
- a chat assistant for investors.

3. Model

```
endpoint: POST /v1/responses
primary model: gpt-5.6-luna
fallback / manual high-quality regeneration: gpt-5.6-terra
store: false
tools: []
text.format: json_schema, strict: true
```

```
Stage 1 (proposals):      reasoning.effort: medium, max_output_tokens: 2500
Stage 2 (analysis text): reasoning.effort: low,      max_output_tokens: 1800
```

The primary model is the lower-cost one. Before launch both stages are tested on a set of example properties. If the quality is not good enough, the platform switches to the higher-quality model. The model name is a setting, so switching requires no development work.

4. Data contracts Bubble → OpenAI

Neither contract contains investor data or the contact details of developer representatives. The numbers, sources and links are examples. The financial figures in the Stage 2 example can be recalculated from the Stage 1 inputs using the formulas in the Database Architecture document. The Rental Yield score (1) follows the score description in the Project Specification (6.3). The other four scores are admin-approved examples, so the Investment Score of 5/10 is illustrative. No verdict label is shown in the example, because the score ranges for the labels have not been decided.

4.1 Stage 1 — property data and source materials

  }
}
}

```

What to notice:

- `source_materials` are the only allowed basis for proposals. Each one has a `source_id`, a link (where one exists) and a date;
- `comparables_summary` lists the `source_ids` it was calculated from, so every comparable behind the range and the median can be checked. It is calculated by Bubble and given for context only;
- `developer_information` is the developer's claim and is never treated as independently verified;
- a requested figure without supporting sources is returned as a gap, and a requested score as `needs_review` with no score — never as 0;
- `scoring_rubric` carries the score descriptions from the Project Specification (6.3). The country examples given there for Owner Protection are left out on purpose: the score must come from the property's own sources;
- `demand_scale` tells the model which Rental Demand scale to use. Which scale applies to a property suitable for both long-term and short-term rental is still to be decided.

4.2 Stage 2 — approved figures, assessments and score

This is sent only after the admin has approved the Stage 1 values and Bubble has calculated the figures and the Investment Score. It carries every component of the calculation and the admin-approved explanation and sources for each criterion score.

The financial figures and the Rental Yield score in the example are calculated as follows:

Figure	Calculation	Result
Purchase costs	$10\% \times €280,000 + €1,500$	€29,500
Total acquisition cost	$€280,000 + €29,500$	€309,500
Annual gross rent	$€1,900 \times 12$	€22,800
Annual effective rent	$€22,800 \times (1 - 0.10)$	€20,520
Annual operating costs	$€2,052 + €1,200 + €300 + €600$	€4,152
Annual net income	$€20,520 - €4,152$	€16,368
Gross yield	$€22,800 / €280,000$	8.14%
Net yield	$€16,368 / €309,500$	5.29%
Estimated fair market value	$78 \text{ m}^2 \times €4,500$	€351,000
Position versus market value	$(€309,500 - €351,000) / €351,000$	11.8% below
Rental Yield score	5.29% is in the "4-6% netto yield" band	1
Investment Score	$2 + 1 + 1 + 1 + 0$	5 / 10

What to notice:

- every figure in `financials` and `score` has been approved by the admin or calculated by Bubble from approved values, and all components of each calculation are included;
- `approved_assessments` carries the admin-approved explanation and sources for each criterion score that needs judgement, so the text can explain the scores without guessing;
- every `source_id` used in `financials` or `approved_assessments` is listed in `sources` or `approved_facts`, or is an `analysis_facts` key;
- `score.components` contains exactly **five** items with keys `price`, `rental_yield`, `rental_demand`, `capital_growth`, `owner_protection`; each score is 0, 1 or 2, and `total` is their sum (0-10);
- `verdict` is empty until the score ranges for the five labels are decided;
- the `analysis_facts` array carries tags `source` / `developer` / `estimate` / `gap` — the model may cite them as sources and **must** mention every `gap` fact under risks or missing_data;
- `rental_demand` carries `demand_scale`, so the text names the scale the score was given on.

Do not send, in either stage:

- investor identity/contact;
- contact details of developer representatives;
- developer verification documents;
- exact private address;
- admin private notes;
- unpublished competing units;
- Make/Bubble secrets;
- full legal text where a versioned disclaimer key is enough.

5. System/developer prompts

These instructions are fixed in the platform and cannot be changed by developers or investors. The property JSON is passed as `input_text` after the instructions. Do not mix the prompt and the data in one free-text block.

5.1 Stage 1 — proposals

Prompt version: `bip-proposals-v1`.

You prepare proposed inputs and assessments for Best Invest Properties. An admin reviews everything you return; nothing is published or used without approval.

Use only the property data and the `source_materials` in the supplied JSON. Do not use outside knowledge. Never invent figures, sources, market conditions, legal rules, taxes, demand or future appreciation.

For each requested item, propose a value only if the `source_materials` support it, and cite the `source_ids` you used. List your assumptions. If the sources do not support a value, return value null with status "gap" and add the item to `missing_data`.

`developer_information` is the developer's claim, never independently verified. Never use the developer's claimed rent as the expected rent.

Do not calculate acquisition cost, yield, net income or the Investment Score, and do not score Rental Yield; the platform does this.

For `estimated_fair_market_value`, use only the comparable properties in the `source_materials` and add a `reliability_note` on the quality of that evidence.

Score Price, Rental Demand, Capital Growth and Owner Protection & Eviction Efficiency with 0, 1 or 2 only, using the descriptions in `scoring_rubric` and the evidence in the sources, not opinion. For Rental Demand use the scale named in `demand_scale`. Never derive Owner Protection from the country alone. If the evidence is insufficient to choose a score, return status "needs_review" with value null and say what is missing; never use 0 for missing data.

Return only JSON matching the supplied strict schema.

5.2 Stage 2 — analysis text

Prompt version: `bip-investment-analysis-v1`.

You write factual investment-property analysis for Best Invest Properties.

Use only facts present in the supplied JSON. Never calculate, infer, estimate, round, or replace financial values. Never invent market conditions, legal rules, taxes, neighbourhood claims, demand, future appreciation, guarantees, or advice.

The financial figures and the Investment Score with its five criterion scores are approved inputs. Explain them; do not challenge or change them. Explain each criterion score only with its approved explanation and sources in `approved_assessments`; never add reasons of your own. There are exactly five criteria, each scored 0, 1 or 2, and the Investment Score is out of 10; never invent, merge, or omit one. If verdict is empty, do not name a verdict label.

Every strength and risk must cite one or more `source_keys` that exist in the input (a `source_id`, an assessment key, or a fact key). If evidence is missing, add the key to

missing_data rather than guessing.
Any analysis_fact tagged "gap" must appear either in risks or in missing_data.
Facts tagged "developer" must be attributed to the developer and never presented as independently verified.

Use neutral, professional language. Avoid certainty about returns. Do not use "guaranteed", "safe", "best", "will increase", "risk-free", or equivalent claims. State clearly that projected and actual returns may differ, that all financial figures are estimates based on the displayed assumptions, and that the content is not financial, tax, or legal advice.

Return only JSON matching the supplied strict schema.

6. Structured Output schemas

OpenAI must answer in exactly these structures. Any answer in a different shape is rejected automatically.

6.1 Stage 1 — proposals

```
{
  "name": "proposed_inputs",
  "strict": true,
  "schema": {
    "type": "object",
    "additionalProperties": false,
    "properties": {
      "schema_version": { "type": "string", "enum": ["1.0"] },
      "proposals": {
        "type": "array",
        "items": {
          "type": "object",
          "additionalProperties": false,
          "properties": {
            "item_key": {
              "type": "string",
              "enum": [
                "expected_monthly_rent",
                "annual_operating_costs",
                "purchase_costs",
                "estimated_fair_market_value",
                "score.price",
                "score.rental_demand",
                "score.capital_growth",
                "score.owner_protection"
              ]
            },
            "status": { "type": "string", "enum": ["proposed", "gap", "needs_review"] },
            "value": { "type": ["number", "null"] },
            "unit": { "type": "string", "enum": ["EUR_per_month", "EUR_per_year", "EUR", "score"] },
            "demand_scale": { "type": "string", "enum": ["long_term", "short_term", "not_applicable"] }
          }
        }
      }
    }
  },
}
```

```

    "breakdown": {
      "type": "array",
      "items": {
        "type": "object",
        "additionalProperties": false,
        "properties": {
          "label": { "type": "string" },
          "amount": { "type": "number" },
          "source_ids": { "type": "array", "items": { "type": "string" } }
        },
        "required": ["label", "amount", "source_ids"]
      }
    },
    "rationale": { "type": "string" },
    "assumptions": { "type": "array", "items": { "type": "string" } },
    "reliability_note": { "type": "string" },
    "source_ids": { "type": "array", "items": { "type": "string" } }
  },
  "required": ["item_key", "status", "value", "unit", "demand_scale", "breakdown",
"rationale", "assumptions", "reliability_note", "source_ids"]
}
},
"missing_data": { "type": "array", "items": { "type": "string" } }
},
"required": ["schema_version", "proposals", "missing_data"]
}
}

```

After parsing, the platform checks that:

- every requested item appears exactly once;
- a `proposed` item has a value and at least one `source_id` that exists in the input;
- a `gap` (figure) or `needs_review` (score) item has `value: null` and appears in `missing_data`;
- the proposed rent is not simply the developer's claimed rent;
- a score is exactly 0, 1 or 2, and only the four `score.*` items carry a score;
- `score.rental_demand` states the scale in `demand_scale` (`long_term` or `short_term`); other items use `not_applicable`;
- a `score.owner_protection` proposal cites at least one source about the property's own situation, not the country alone.

The proposals are then saved as **"awaiting review"** for the admin.

6.2 Stage 2 — analysis text

```

{
  "name": "investment_analysis",
  "strict": true,
  "schema": {
    "type": "object",
    "additionalProperties": false,
    "properties": {
      "schema_version": { "type": "string", "enum": ["1.0"] },
      "headline": { "type": "string" },

```

```

"summary": { "type": "string" },
"strengths": {
  "type": "array",
  "items": {
    "type": "object",
    "additionalProperties": false,
    "properties": {
      "title": { "type": "string" },
      "commentary": { "type": "string" },
      "source_keys": {
        "type": "array",
        "items": { "type": "string" }
      }
    }
  },
  "required": ["title", "commentary", "source_keys"]
},
"risks": {
  "type": "array",
  "items": {
    "type": "object",
    "additionalProperties": false,
    "properties": {
      "title": { "type": "string" },
      "commentary": { "type": "string" },
      "severity": { "type": "string", "enum": ["low", "medium", "high", "unknown"] },
      "source_keys": {
        "type": "array",
        "items": { "type": "string" }
      }
    }
  },
  "required": ["title", "commentary", "severity", "source_keys"]
},
"score_explanation": { "type": "string" },
"missing_data": {
  "type": "array",
  "items": { "type": "string" }
},
"disclaimer_key": { "type": "string", "enum": ["investment_analysis_standard_v1"] }
},
"required": [
  "schema_version",
  "headline",
  "summary",
  "strengths",
  "risks",
  "score_explanation",
  "missing_data",
  "disclaimer_key"
]
}
}

```

After parsing, the platform checks text lengths, 2–4 strengths, 1–4 risks, at least one source key per item, and that no number appears that is not in the input.

Structured Outputs guarantees that the answer has the right structure, but **not** that it is factually correct. That is why the automatic checks and the admin review are always required. Any change to the number of score criteria or to the input structure requires a new prompt version; the schema version changes only when the output structure changes.

7. Request examples (shortened)

7.1 Stage 1 — proposals

```
{
  "model": "gpt-5.6-luna",
  "store": false,
  "reasoning": { "effort": "medium" },
  "max_output_tokens": 2500,
  "metadata": {
    "use_case": "bip_proposed_inputs",
    "prompt_version": "bip-proposals-v1",
    "proposal_id": "prp_01J..."
  },
  "instructions": "<versioned Stage 1 prompt>",
  "input": [
    {
      "role": "user",
      "content": [
        { "type": "input_text", "text": "<property data and source materials JSON>" }
      ]
    }
  ],
  "text": {
    "format": { "type": "json_schema", "name": "proposed_inputs", "strict": true, "schema": "<full schema from 6.1>" }
  }
}
```

7.2 Stage 2 — analysis text

```
{
  "model": "gpt-5.6-luna",
  "store": false,
  "reasoning": { "effort": "low" },
  "max_output_tokens": 1800,
  "metadata": {
    "use_case": "bip_investment_analysis",
    "prompt_version": "bip-investment-analysis-v1",
    "analysis_id": "ana_01J..."
  },
  "instructions": "<versioned Stage 2 prompt>",
  "input": [
    {
```

```

    "role": "user",
    "content": [
      { "type": "input_text", "text": "<approved property snapshot JSON>" }
    ]
  },
  "text": {
    "format": { "type": "json_schema", "name": "investment_analysis", "strict": true, "schema": "
<full schema from 6.2>" }
  }
}

```

In both examples the prompt, the input JSON and the `schema` value are shortened with placeholders. In the real request, `schema` contains the full schema from 6.1 or 6.2, and the prompt and input are sent in full.

The model is not given web search or any other tools, so it cannot bring in facts from outside the supplied data.

How OpenAI keeps the data. Under OpenAI's published data controls:

- `store: false` means the response is **not saved as application state** for later retrieval through the API. It does not mean that OpenAI keeps no record of the request.
- By default, API requests and responses may be kept in **abuse-monitoring logs for up to 30 days**, or longer where required by law or needed to protect OpenAI's services or others from harm.
- Data sent to the API is **not used to train OpenAI models** unless the organisation opts in.
- **Zero Data Retention** is available only to eligible customers approved by OpenAI. Whether the platform needs it is to be decided before launch.
